Introduction To Wireline Logging

The first objective of logging in an exploration area is to locate hydrocarbons in a well. Next, the operating company wants to determine if enough hydrocarbons are present to justify assembling a logging tool on a rig floor. One logging operator holds a logging tool in place (left) while another assembles a connection (right).

During logging runs, a wireline heave compensator was employed to minimize the effect of ship's heave (caused by sea swell) on the motion and position of the tool string in the borehole. Not all tool strings were run in each hole; individual site chapters give details of logging strings deployed at each site.

OPEN HOLE WIRELINE LOGGING Logging operations The log is made by measuring the variation in (rather than the absolute) potential versus depth. Over a typical survey interval these deflections can generally be captured on a scale of 0-100 mV.

Wireline logging can be defined as being "The acquisition and analysis of geophysical data performed as a function of well bore depth, together with the provision of related services." Note that "wireline logging" and "mud logging" are not the same, yet are closely linked through the integration of the data sets.

Although the emphasis is on wireline logging techniques and log analysis methods, these are far from the only tools available to the formation evaluator. Well logs are central only in the sense that they are recorded in practically all wellbores and are directly relatable to all the other parameters available from the associated sciences.

Wireline logging is a conventional form of logging that employs a measurement tool suspended on a cable or wire that suspends the tool and carries the data back to the surface. These logs are taken between drilling episodes and at the end of drilling. Recent developments also allow some measurements to be made during drilling.
